5.2 Nested Vectored Interrupt Controller (NVIC)

5.2.1 Overview

The Cortex-M0 provides an interrupt controller as an integral part of the exception mode, named as “Nested Vectored Interrupt Controller (NVIC)”. It is closely coupled to the processor kernel and provides following features:

5.2.2 Features

- Nested and Vectored interrupt support
- Automatic processor state saving and restoration
- Dynamic priority changing
- Reduced and deterministic interrupt latency

The NVIC prioritizes and handles all supported exceptions. All exceptions are handled in “Handler Mode”. This NVIC architecture supports 32 (IRQ[31:0]) discrete interrupts with 4 levels of priority. All of the interrupts and most of the system exceptions can be configured to different priority levels. When an interrupt occurs, the NVIC will compare the priority of the new interrupt to the current running one’s priority. If the priority of the new interrupt is higher than the current one, the new interrupt handler will override the current handler.

When any interrupts is accepted, the starting address of the interrupt service routine (ISR) is fetched from a vector table in memory. There is no need to determine which interrupt is accepted and branch to the starting address of the correlated ISR by software. While the starting address is fetched, NVIC will also automatically save processor state including the registers “PC, PSR, LR, R0~R3, R12” to the stack. At the end of the ISR, the NVIC will restore the mentioned registers from stack and resume the normal execution. Thus it will take less and deterministic time to process the interrupt request.

The NVIC supports “Tail Chaining” which handles back-to-back interrupts efficiently without the overhead of states saving and restoration and therefore reduces delay time in switching to pending ISR at the end of current ISR. The NVIC also supports “Late Arrival” which improves the efficiency of concurrent ISRs. When a higher priority interrupt request occurs before the current ISR starts to execute (at the stage of state saving and starting address fetching), the NVIC will give priority to the higher one without delay penalty. Thus it advances the real-time capability.

5.11 I²C

5.11.1 Overview

I²C is a two-wire, bi-directional serial bus that provides a simple and efficient method of data exchange between devices. The I²C standard is a true multi-master bus including collision detection and arbitration that prevents data corruption if two or more masters attempt to control the bus simultaneously. Serial, 8-bit oriented bi-directional data transfers can be made up to 1.0 Mbps.

Data is transferred between a Master and a Slave synchronously to SCL on the SDA line on a byte-by-byte basis. Each data byte is 8-bit long. There is one SCL clock pulse for each data bit with the MSB being transmitted first. An acknowledge bit follows each transferred byte.

A transition on the SDA line while SCL is high is interpreted as a command (START or STOP). Each bit is sampled during the high period of SCL; therefore, the SDA line may be changed only during the low period of SCL and must be held stable during the high period of SCL.

The controller's on-chip I²C logic provides the serial interface that meets the I²C bus standard mode specification. The I²C controller handles byte transfers autonomously. Pull up resistor is needed for I²C operation as these are open drain pins.

The I²C controller is equipped with two slave address registers. The contents of the registers are irrelevant when I²C is in Master mode. In the Slave mode, the seven most significant bits must be loaded with the user's own slave address. The I²C hardware will react if the contents of I2CADDR are matched with the received slave address.

This controller supports the "General Call (GC)" function. If the GC bit is set this controller will respond to General Call address (00H). Clear GC bit to disable general call function. When GC bit is set and the I²C is in Slave mode, it can receive the general call address which is equal to 00H after master sends general call address to the I²C bus, then it will follow status of GC mode. If it is in Master mode, the ACK bit must be cleared when it sends general call address of 00H to the I²C bus.

The I²C-bus controller supports multiple address recognition with two address mask register. When the bit in the address mask register is set to one, it means the received corresponding address bit is don't-care. If the bit is set to zero, that means the received corresponding register bit should be exact the same as address register.

5.11.2 Features

- Acts as Master or Slave mode
- Bidirectional data transfer between masters and slaves
- Multi-master bus (no central master)
- Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
- Serial clock synchronization allows devices with different bit rates to communicate via one serial bus

5.13 LCD Display Driver

5.13.1 Overview

The LCD driver can directly drive a LCD glass by creating the ac segment and common voltage signals automatically. It can support static, 1/2 duty, 1/3 duty, 1/4 duty, 1/5 duty and 1/6 duty LCD glass with up to 38 segments with 6 COM (segment 0 is used as LCD_COM4 and segment 1 is used as LCD_COM5) or 40 segments with 4 COM (LCD_COM0 ~ LCD_COM3).

A built-in charge pump function can be enabled to provide the LCD glass with higher voltage than the system voltage. The LCD driver would generate voltage higher than the threshold voltage in older to darken a segment and a voltage lower than threshold to make a segment clear. However, the LCD display segment will degrade if the applied voltage has a DC-component. To avoid this, the generated waveform by LCD driver are arranged such that average voltage of each segment is zero and the RMS(root-mean-square) voltage applied on a LCD segment lower than the segment threshold making LCD clear and RMS voltage higher than the segment threshold making LCD dark.

Note : Output voltage for ADC/LCD shared pins cannot be higher than VDD because these pins are without 5V tolerance.

5.14.1 Overview

This chip has two PWM controllers, each controller has 4 independent PWM outputs, CH0~CH3, or as 2 complementary PWM pairs, (CH0, CH1), (CH2, CH3) with 2 programmable dead-zone generators.

Each two PWM outputs, (CH0, CH1), (CH2, CH3), share the same 8-bit prescaler, clock divider providing 5 divided frequencies (1, 1/2, 1/4, 1/8, 1/16). Each PWM output has independent 16-bit PWM down-count counter for PWM period control, and 16-bit comparators for PWM duty control. Each dead-zone generator has two outputs. The first dead-zone generator output is CH0 and CH1, and for the second dead-zone generator, the output is CH2 and CH3. The 2 sets of PWM controller total provide eight independent PWM interrupt flags which are set by hardware when the corresponding PWM period down counter reaches zero. PWM interrupt will be asserted when both PWM interrupt source and its corresponding enable bit are active. Each PWM output can be configured as one-shot mode to produce only one PWM cycle signal or continuous mode to output PWM waveform continuously.

When DZEN01 of PWMx_CTL is set, CH0 and CH1 perform complementary PWM paired function; the paired PWM timing, period, duty and dead-time are determined by PWM channel 0 timer and Dead-zone generator 0. Similarly, When DZEN23 of PWMx_CTL is set the complementary PWM pair of (CH2, CH3) is controlled by PWM channel 2.

To prevent PWM driving output pin with unsteady waveform, the 16-bit period down counter and 16-bit comparator are implemented with double buffer. When user writes data to counter/comparator buffer registers the updated value will be loaded into the 16-bit down counter/ comparator at the time down counter reaching zero. The double buffering feature avoids glitch at PWM outputs.

When the 16-bit period down counter reaches zero, the interrupt request is generated. If PWM output is set as continuous mode, when the down counter reaches zero, it is reloaded with CN of PWMx_DUTYy(y=0~3) Register automatically then start decreases, repeatedly. If the PWM output is set as one-shot mode, the down counter will stop and generate one interrupt request when it reaches zero.

The value of PWM counter comparator is used for pulse width modulation. The counter control logic changes the output level when down-counter value matches the value of compare register.

The alternate feature of the PWM is digital input capture function. If capture function is enabled the PWM output pin is switched as capture input pin. The capture channel 0 and PWM CH0 share one timer; and the capture channel 1 and PWM CH1 share one timer, and etc. Therefore user must setup the PWM timer before enabling capture feature. After capture feature is enabled, the capture always latches PWM timer to Capture Rising Latch Register (PWMx_CRLy) where y=0~3, when input channel has a rising transition and latches PWM timer to Capture Falling Latch Register (PWMx_CFLy) where y=0~3, when input channel has a falling transition. Capture channel 0 interrupt is programmable by setting PWMx_CAPINTEN. Whenever Capture event latched for channel 0/1/2/3, the PWM timer 0/1/2/3 will be reload at this moment if the corresponding reload enable bit specified in CAPCTL are set.

The maximum captured frequency that PWM can capture is dominated by the capture interrupt latency. When capture interrupt occurs, software will do at least three steps, they are: Read PWMINTSTS to tell it from interrupt source and Read PWMx_CRLy/PWMx_CFLy(y=0~3) to get capture value and finally write 1 to clear PWMx_INTSTS. If interrupt latency will take time T0 to finish, the capture signal mustn't transient during this interval. In this case, the maximum capture frequency will be 1/T0.

5.19 UART Controller

5.19.1 Overview

The UART controllers provides up to two channels of Universal Asynchronous Receiver/Transmitter (UART) modules that are UART0 and UART1. (UART0 is at APB1 and UART1 is at APB2).

The Universal Asynchronous Receiver/Transmitter (UART) performs a serial-to-parallel conversion on data received from the peripheral, and a parallel-to-serial conversion on data transmitted from the CPU. The UART controller also supports IrDA (SIR) function mode, LIN Master/Slave function mode and RS-485 function mode. Each UART channel supports nine types of interrupts including receiver threshold level reaching interrupt (INT_RDA), transmitter FIFO empty interrupt (INT_THRE), line status interrupt (break error, parity error, framing error or RS-485 interrupt) (INT_RLS), time-out interrupt (INT_TOUT), MODEM status interrupt (INT_MODEM), Buffer error interrupt (INT_BUF_ERR), wake-up interrupt (INT_WAKE), auto-baud rate detect or auto-baud rate counter overflow flag (INT_ABAUD) and LIN function interrupt (INT_LIN).

The UART0 and UART1 are built-in with a 16-byte transmitter FIFO (TX_FIFO) and a 16-byte receiver FIFO (RX_FIFO) that reduces the number of interrupts presented to the CPU. The CPU can read the status of the UART at any time during the operation. The reported status information includes the type and condition of the transfer operations being performed by the UART, as well as 3 error conditions (parity error, framing error or break interrupt) occur while receiving data. The UART controller supports auto-baud rate detection. The auto-baud rate detection controls the process of measuring the incoming clock/data rate for the baud rate generation and can be read and written at user discretion. The UART controller also support incoming data or CTSn wake-up function. When the system is in power-down mode, an incoming data or CTSn signal will wake-up CPU from power-down mode. The UART includes a programmable baud rate generator that is capable of dividing crystal clock input by divisors to produce the clock that transmitter and receiver need. The baud rate equation is Baud Rate = UART_CLK / [BRD + 1], where BRD are defined in UART Baud Rate Divider Register (UARTx_BAUD). Below table lists the equations in the various conditions and the UART baud rate setting table.

DIV_16_EN	BRD	Baud Rate Equation
Disable (Mode 0)	A	UART_CLK / (A+1), A must >8
Enable (Mode 1)	A	UART_CLK / [16 * (A+1)]

5.19.1.1 Auto-Flow Control

The UART0 and UART1 controllers support auto-flow control function that uses two low-level signals, CTSn (clear-to-send) and RTSn (request-to-send) to control the flow of data transfer between the UART and external devices (ex: Modem). When auto-flow is enabled, the UART is not allowed to receive data until the UART asserts RTSn (RTSn high) to external device. When the number of bytes in the RX-FIFO equals the value of UART_TLCTL [RTS_TRI_LEV], the RTSn is de-asserted. The UART sends data out when UART controller detects CTSn is asserted (CTSn high) from external device. If a valid asserted CTSn is not detected the UART controller will not send data out.

5.19.1.2 Auto-Baud Rate Detection

The UART0 and UART1 controllers support auto-baud rate detection. The auto-baud rate function can be used to measure the receiver incoming data baud rate. If enabled the auto-baud feature, UART controller will measure the bit time of the received data stream and set the divisor latch registers UART_BARD. Auto-baud rate detection is started by setting the UART_CTL [ABAUD_EN].

5.19.1.3 UART Wake-Up Function

The UART0 and UART1 controllers support wake-up system function. The wake-up function includes CTSn wake-up function (UART_CTL [WAKE_CTS_EN]) and data wake-up function (UART_CTL [WAKE_DATA_EN]). When the system is operation in power-down mode, the UART can wake-up system by CTSn pin or by incoming data.

5.19.1.4 IrDA Function Mode

The UART controllers also provides Serial IrDA (SIR, Serial Infrared) function (User must set UART_FUN_SEL to select IrDA function). The SIR specification defines a short-range infrared asynchronous serial transmission mode with one start bit, 8 data bits, and 1 stop bit. The maximum data rate is 115.2 Kbps (half duplex). The IrDA SIR block contains an IrDA SIR Protocol encoder/decoder. The IrDA SIR protocol is half-duplex only. So it cannot transmit and receive data at the same time. The IrDA SIR physical layer specifies a minimum 10 ms transfer delay between transmission and reception, and in IrDA Operation mode the UART_BAUD setting must be mode1 (UART_BAUD [DIV_16_EN] = “1”).

5.19.1.5 RS-485 Function Mode

Another alternate function of UART controllers is RS-485 9 bit mode function whose direction control can be controlled by RTSn pin or GPIO. The RS-485 function mode is selected by setting the UART_FUN_SEL register to select RS-485 function. The RS-485 driver control is implemented by using the RTSn control signal from an asynchronous serial port to enable the RS-485 driver. In RS-485 mode, many characteristics of the RX and TX are same as UART.

5.19.1.6 LIN Function Mode

5.19.2 The LIN mode is selected by setting the LIN_EN bit in UART_FUN_SEL register. In LIN mode, one start bit and 8-bit data format with 1-bit stop bit are required in accordance with the LIN standard. Features

5.20 USB

5.20.1 Overview

The USB controller is a USB 2.0 full-speed device controller. It is compliant with USB 2.0 full speed device specification and supports control/bulk/interrupt/isochronous transfer types.

In this device controller, there are two main interfaces: the APB bus and USB bus which comes from the USB PHY transceiver. For the APB bus, the CPU can program control registers through it. There is an internal 512-byte SRAM as data buffer in this controller. For IN token or OUT token transfer, it is necessary to write data to SRAM or read data from SRAM through the APB interface. Users need to allocate the effective starting address of SRAM for each endpoint buffer through “buffer segmentation register (BUFSEG)”.

This device controller contains 8 configurable endpoints. Each endpoint can be configured as IN or OUT endpoint. The function address of the device and endpoint number in each endpoint shall be configured properly in advance for receiving or transmitting a data packet correctly. The transmitting/receiving length in each endpoint is defined in maximum payload register (MXPLD) and the handshakes between Host and Device are also handled by it.

There are four different interrupt events in this controller. They are the wake-up function, device plug-in or plug-out event, USB events, like IN ACK, OUT ACK etc, and BUS events, like suspend and resume, etc. Any event will cause an interrupt, and users just need to check the related event flags in interrupt event status register (USB_INTSTS) to acknowledge what kind of events occurring, and then check the related USB Endpoint Status Register (USB_EPSTS) to acknowledge what kind of event occurring in this endpoint.

A software-disable function is also supported for this USB controller. It is used to simulate the disconnection of this device from the host. If user enables the DRVSE0 bit (USB_CTL[4]), the USB controller will force USB_DP and USB_DM to level low and USB device function is disabled (disconnected). After disable the DRVSE0 bit, USB_DP will be pulled high by internal pull-high circuit then host will enumerate the USB device connection again.

7 APPLICATION CIRCUIT

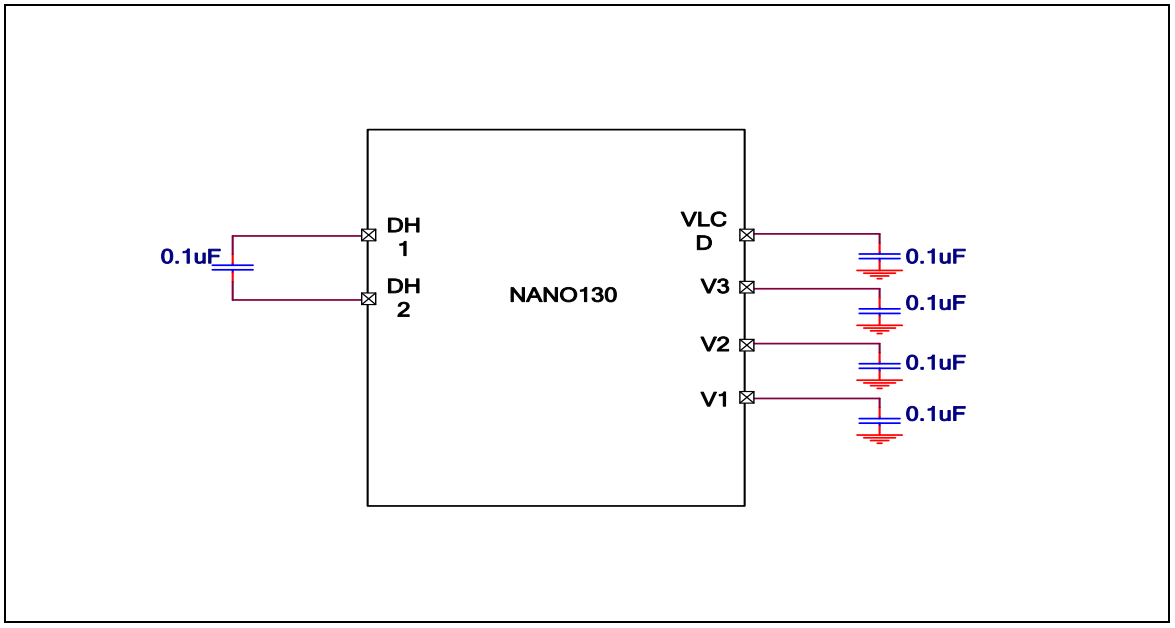
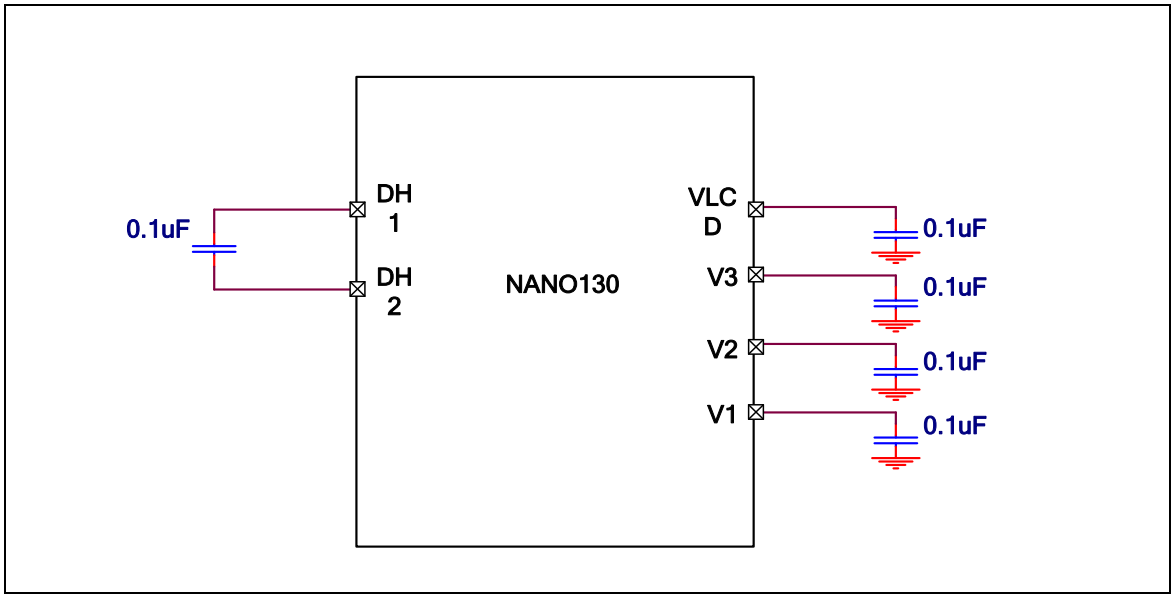
7.1.1 C-type 1/3 Bias

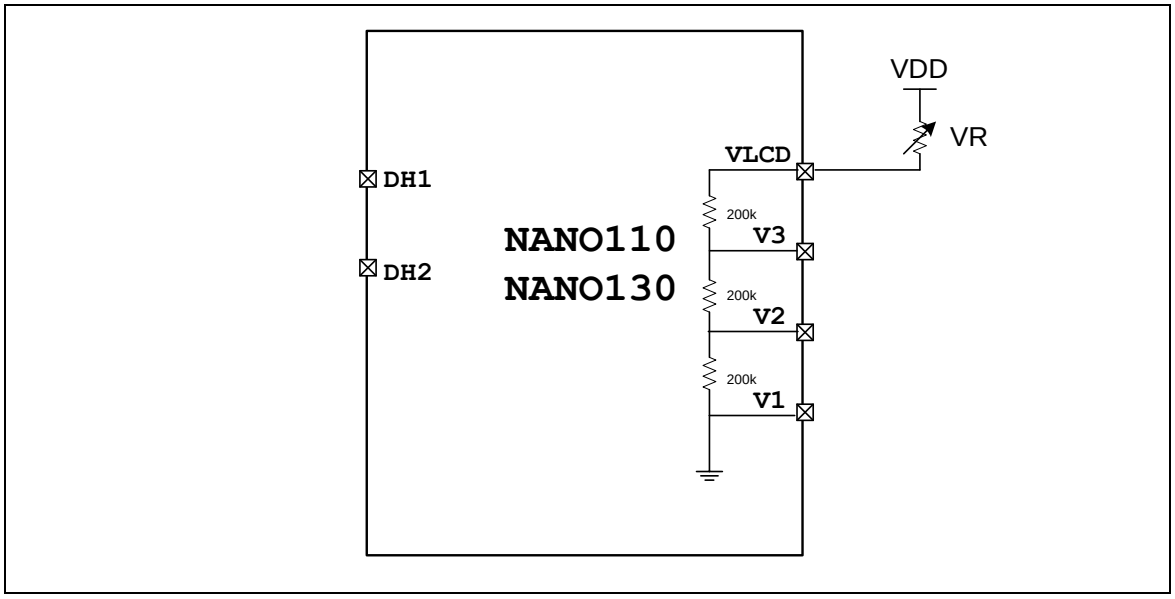


7.1.2 C-type 1/2 Bias



7.1.3 Internal R-type

Nano110/130 series MCUs also support external R-type mode (bypass internal R) to reduce current consumption. For external R-type application, VLCD is normally connected to system VDD, or it can be connected to VDD through an external variable resistor (VR) which is used for adjusting LCD contrast.



7.1.4 External R-type

To reduce the current, the resistor ladder value can be increased. At some point, when the resistor ladder value is increased, the contrast will become affected and the waveform shape will be altered. Therefore, capacitors around 0.1uF should be chosen and place closed to resistor ladder based on the contrast and size of the pixels on the glass.

1. /RESET pin is a Schmitt trigger input.
2. Crystal Input is a CMOS input.
3. It is recommended that a 10uF or higher capacitor and a 100nF bypass capacitor are connected between VDD and the closest VSS pin of the device.
4. For ensuring power stability, a 4.7uF or higher capacitor must be connected between LDO pin and the closest VSS pin of the device. Also a 100nF bypass capacitor between LDO and VSS help suppressing output noise.
5. All peripherals' clock source is from HXT (12 MHz), except SPI from HCLK.
